A total of 702 isolates (incidental 126, organ/space 374 strains) were included in the investigation. E. coli (20.4%) and Enterococcus faecalis (19.5%) were the most common isolates. Pseudomonas aeruginosa (14.5%) and Bacteroides fragilis group (13.5%) were next with Enterobacter cloacae, Enterobacter cloacae and Klebsiella pneumoniae accounted for 15.5%, 8.8%, and 7.1% of isolates, respectively. These hundreds thirty-six strains were isolated from lower gastrointestinal surgery, 100 strains from hepatobiliary and pancreatic surgery, 71 strains from upper gastrointestinal surgery, 68 strains from general surgery including breast surgery, and 50 strains from thoracic surgery (ammonium and respiratory tract). Leading isolates were E. coli in upper gastrointestinal surgery, general surgery and thoracic surgery. Enterococcus faecalis in hepatobiliary and pancreatic surgery and B. fragilis in lower gastrointestinal surgery among the gastrointestinal surgery.

Conclusions: A total of 702 isolates (incidental 126, organ/space 374 strains) were included in the investigation. E. coli (20.4%) and Enterococcus faecalis (19.5%) were the most common isolates. Pseudomonas aeruginosa (14.5%) and Bacteroides fragilis group (13.5%) were next with Enterobacter cloacae, Enterobacter cloacae and Klebsiella pneumoniae accounted for 15.5%, 8.8%, and 7.1% of isolates, respectively. These hundreds thirty-six strains were isolated from lower gastrointestinal surgery, 100 strains from hepatobiliary and pancreatic surgery, 71 strains from upper gastrointestinal surgery, 68 strains from general surgery including breast surgery, and 50 strains from thoracic surgery (ammonium and respiratory tract). Leading isolates were E. coli in upper gastrointestinal surgery, general surgery and thoracic surgery. Enterococcus faecalis in hepatobiliary and pancreatic surgery and B. fragilis in lower gastrointestinal surgery among the gastrointestinal surgery.
